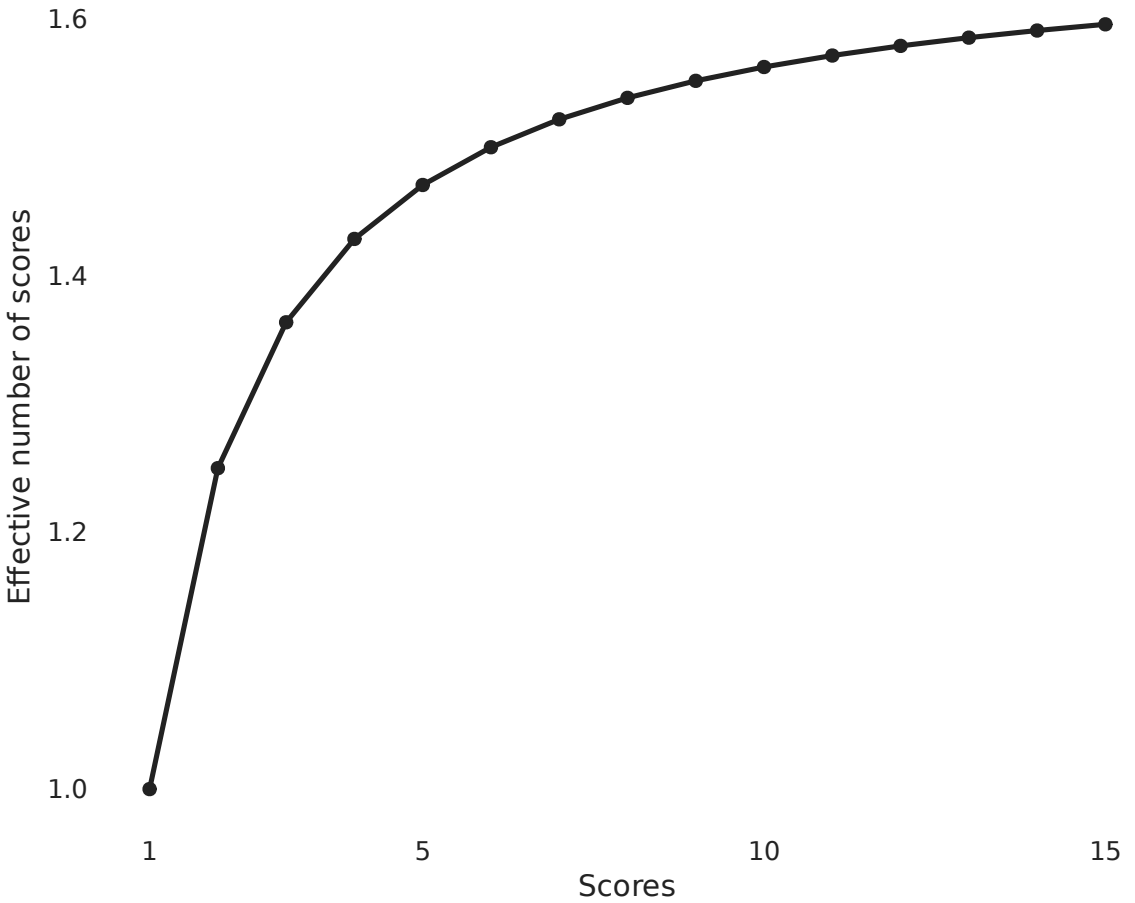
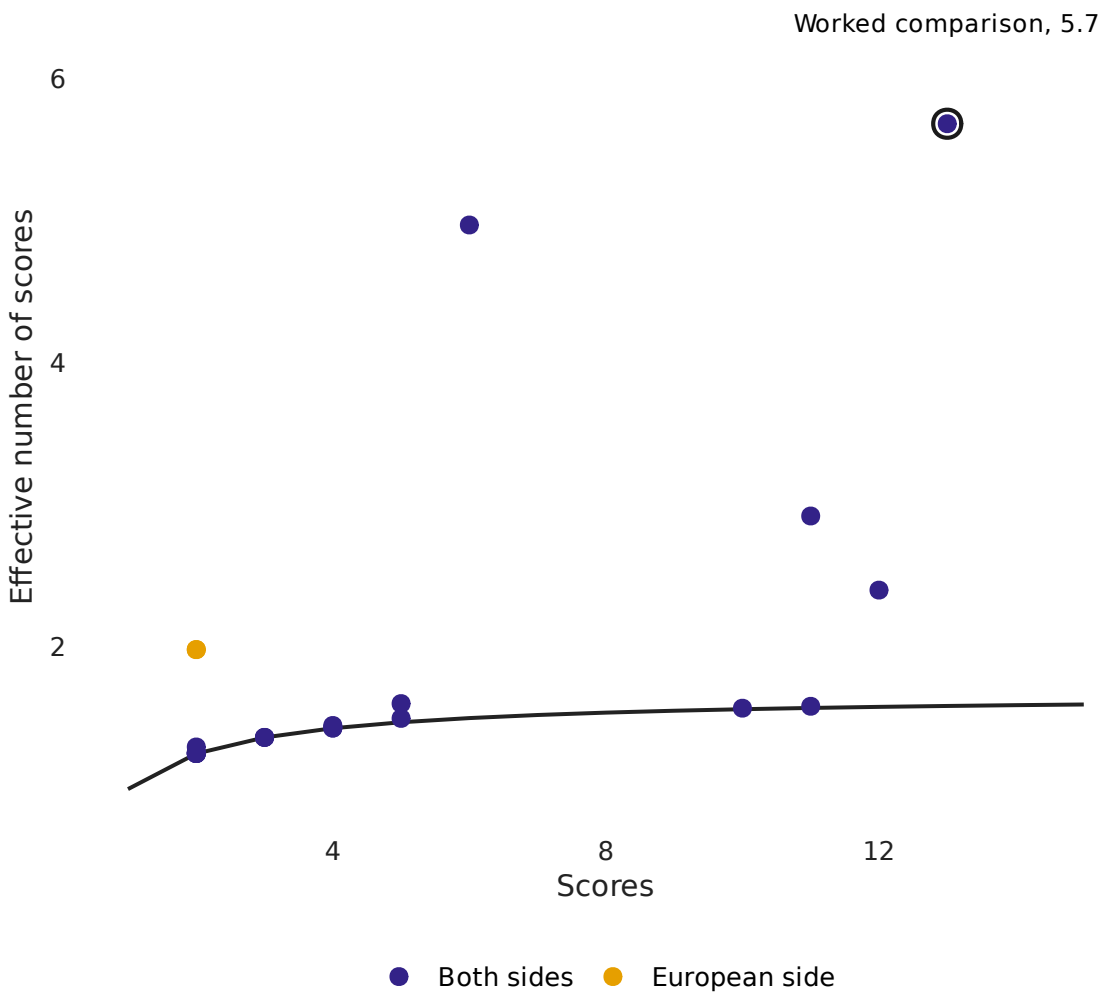
5. What the correlation is worth

Effective number of scores = score count × (plain-average standard error / correlation-only standard error)².

Every score shares one label on both sides



The 24 comparisons at ρ = 0.6



The curve is m / (1 + (m − 1)ρ) at ρ = 0.6. It is the effective number when every score shares one label on both sides, or the shared side carries all of the variance. Comparisons shared on one side sit near the score count, and that is why they fall off the curve. The worked comparison sits above the curve because PGS004106 is uncorrelated with the others.
