1. From evaluations to the estimate

Type 2 diabetes, South Asian participants, European-only training. Counts are every comparison.

Evaluations

32 comparisons. This worked comparison has 13 scores.

Score pair

An ancestry difference, a European standard error, and a non-European standard error.

Labels

Sample sets become study names, then one label on each side.
This comparison is 1 sharing group.

Two calls to vcalc

A European covariance and a non-European covariance, at ρ = 0.6. Their sum is V.

rma.mv

Between-score variance by REML. Here σ^2 = 9.07e-05.

Estimate

This comparison's estimate is 0.004.
24 comparisons with shared people take this path. The other 8 keep the average of all scores.

robust

Reported when the degrees of freedom are at least 4.
23 of the 24 have one sharing group, so the interval is the model interval.
Type 2 diabetes, Hispanic or Latin American participants, Multi-ancestry training has 4 sharing groups and 2.3 degrees of freedom.
Below that threshold, the reported interval is the model interval.

Figure 09

Draws the average of all scores and this model at ρ = 0.6.

12 of the 24 comparisons with shared people have 2 or 3 scores, so the between-score variance is flagged unstable.
