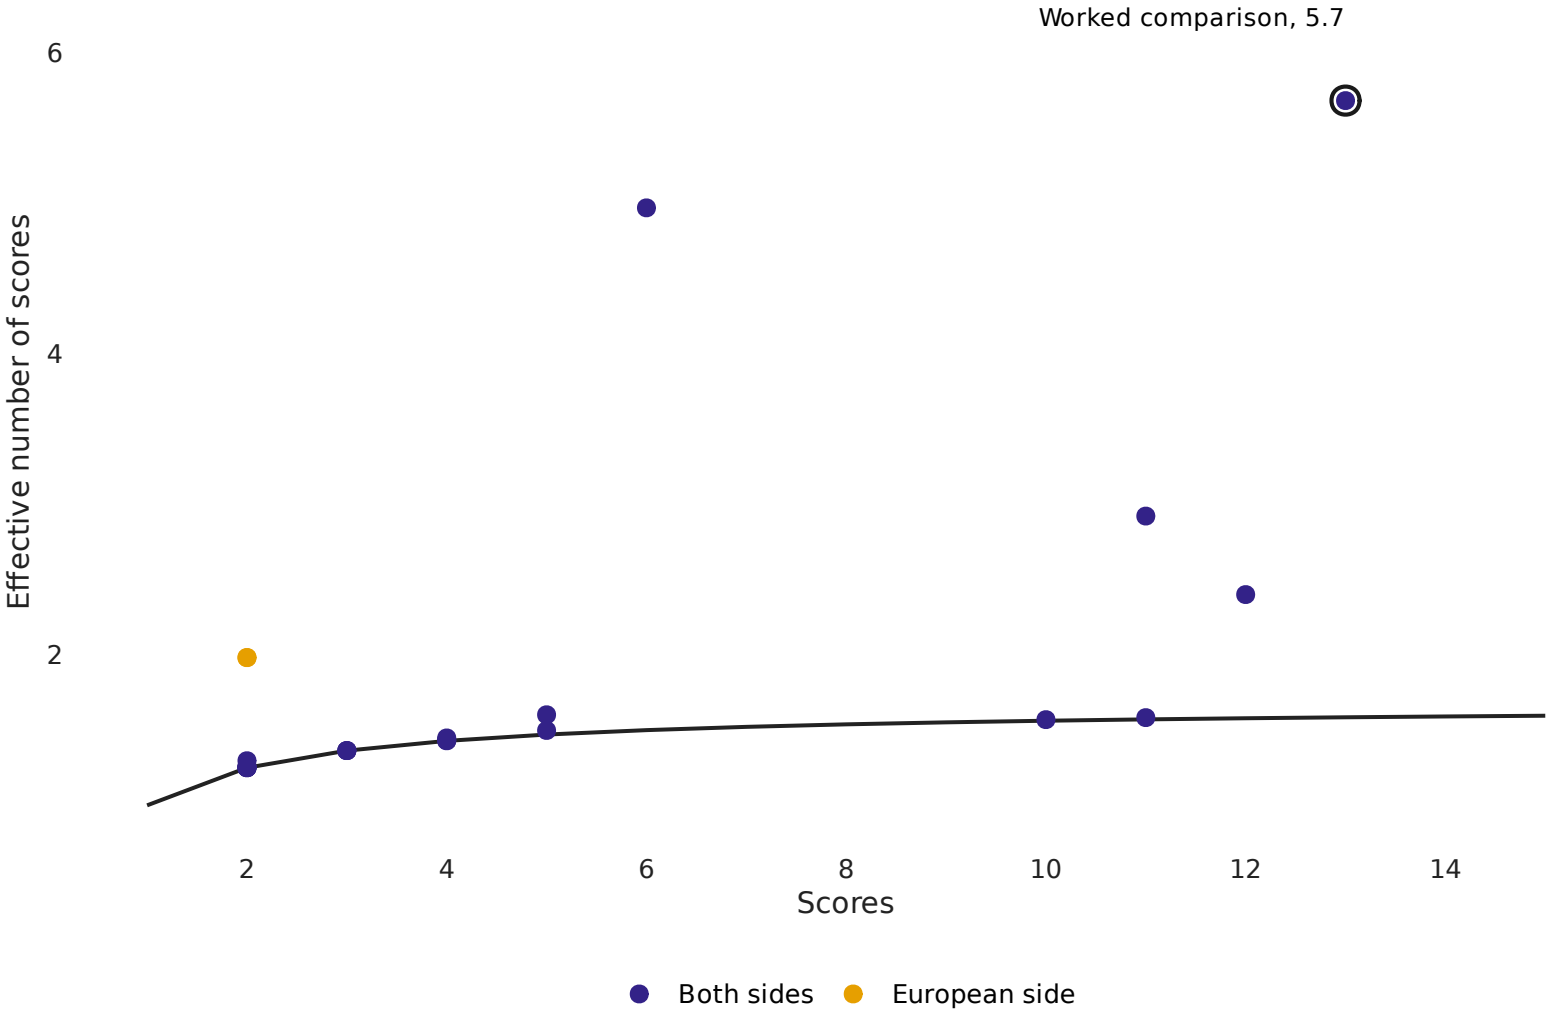
## 5. What the correlation is worth

Effective number of scores = score count × (plain-average standard error / correlation-only standard error)².



The curve is m / (1 + (m − 1)ρ) at ρ = 0.6. It is the effective number when every score shares one label on both sides, or the shared side carries all of the variance. Comparisons shared on one side sit near the score count, and that is why they fall off the curve. Points above the curve contain scores without a shared exact label. The worked comparison is one of them: PGS004106 is uncorrelated with the others.
