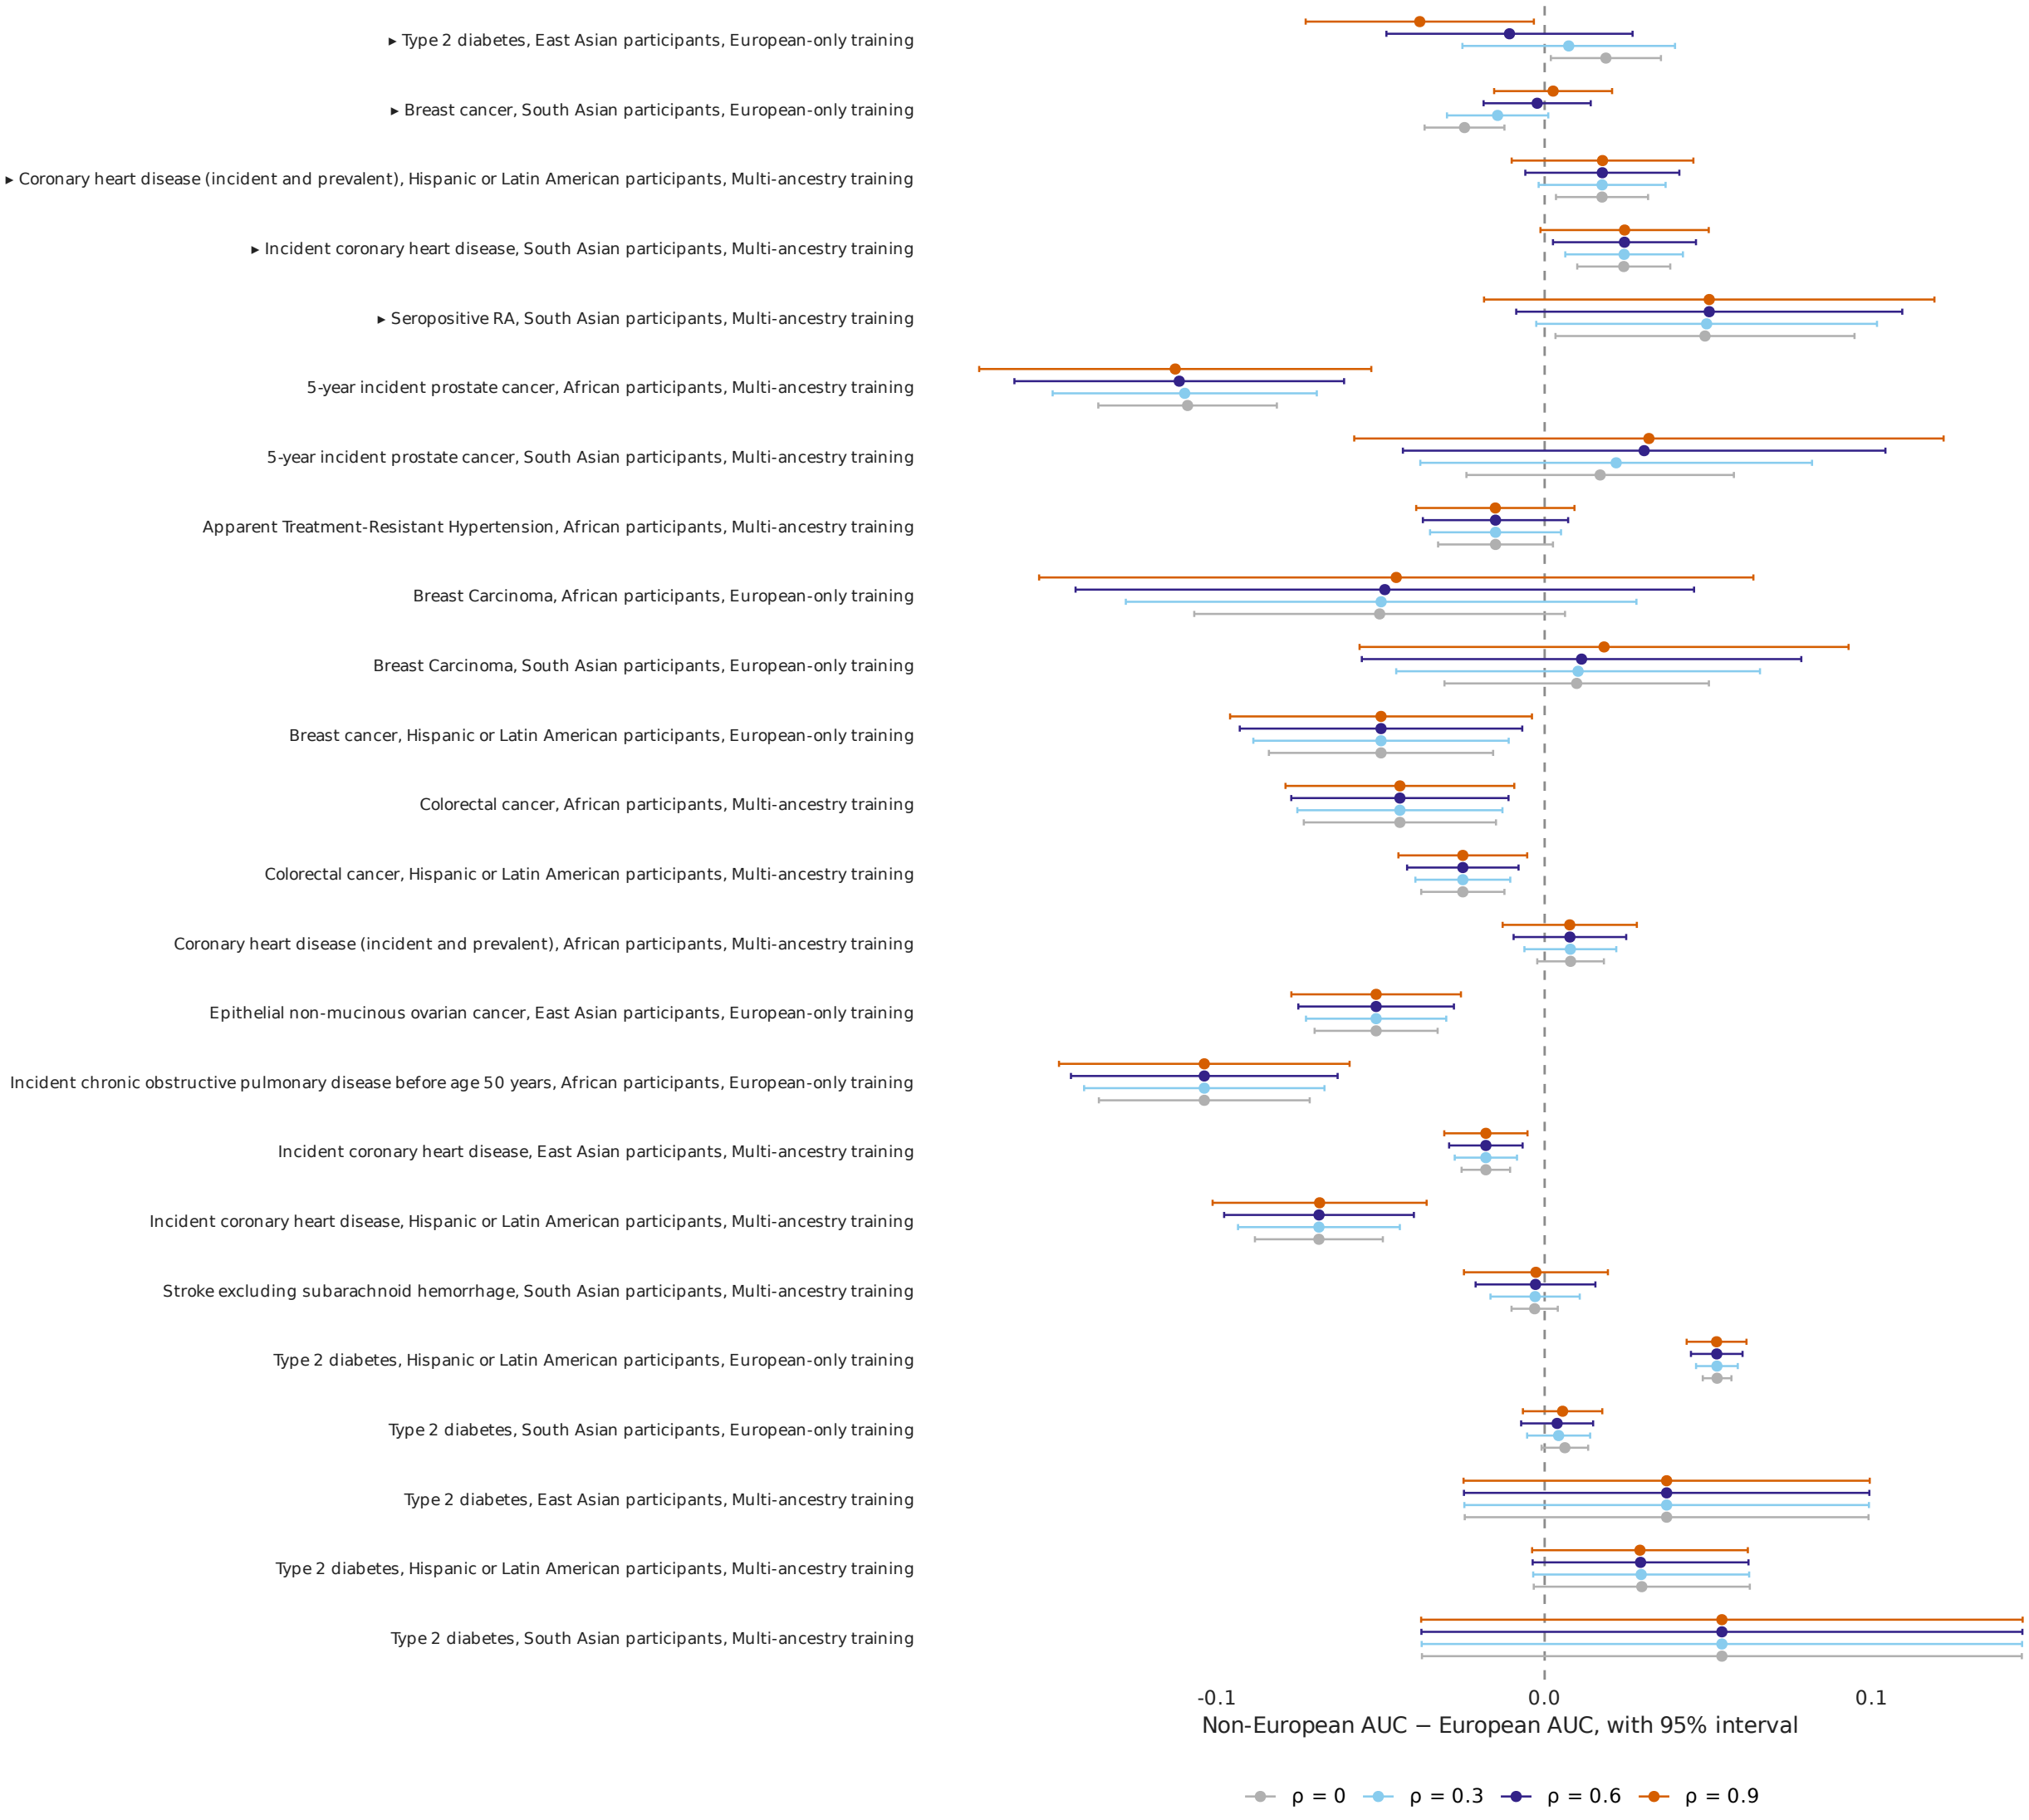
9. The same comparisons at four values of ρ

A triangle in the label marks a comparison whose zero call changes. The reported intervals use ρ = 0.6.



Five comparisons change whether the interval excludes zero from ρ = 0 to ρ = 0.9. Three change only between 0 and 0.3: Breast cancer, South Asian participants, European-only training; Coronary heart disease (incident and prevalent), Hispanic or Latin American participants, Multi-ancestry training; Seropositive RA, South Asian participants, Multi-ancestry training.

Two still change between 0.3 and 0.9: Incident coronary heart disease, South Asian participants, Multi-ancestry training (excludes zero at ρ = 0.3 and 0.6, and includes zero at ρ = 0.9); Type 2 diabetes, East Asian participants, European-only training (includes zero at ρ = 0.3 and 0.6, and excludes zero at ρ = 0.9).

Type 2 diabetes, East Asian participants, European-only training excludes zero at ρ = 0 with estimate 0.019, and excludes zero again at ρ = 0.9 with estimate -0.038. The sign reverses. Large ρ makes the weights extreme as V becomes nearly singular. It is not a narrower interval around the same estimate, and it is not stronger evidence. Figure 11 shows the two comparisons whose intervals narrow as ρ rises.
