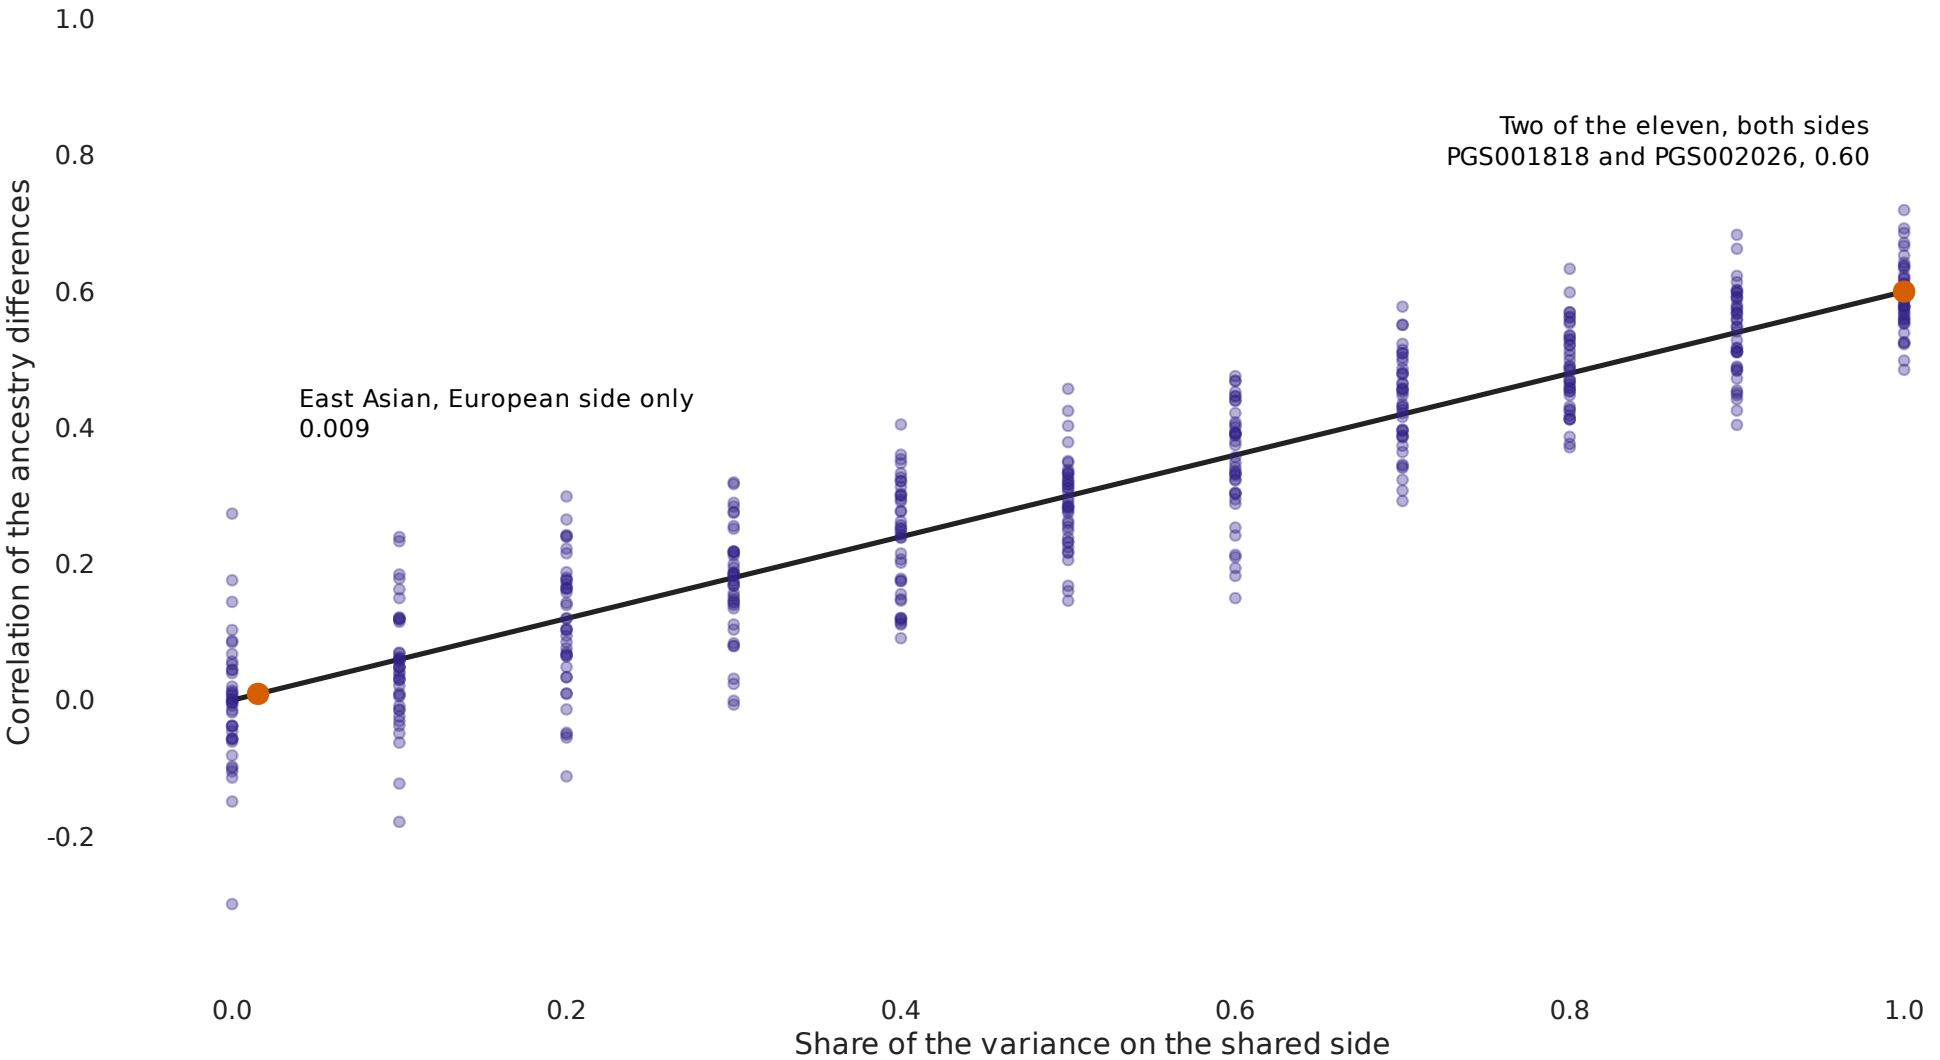
10. What ρ means

ρ is the correlation of two scores' AUC errors on one side with the same label.



For two scores with equal standard errors, the correlation of the ancestry differences is exactly ρ times the shared side's share of the variance. The line is that rule. The blue points are sampling scatter around it, from a fixed seed.

Two of the eleven share a label on both sides (PGS001818 and PGS002026), so the correlation of their differences is 0.60.

Type 2 diabetes, East Asian participants, multi-ancestry training shares on the European side only, and the correlation of the differences is 0.009, because the European standard errors are tiny. Both real pairs sit on the line.

This is a sampling model. It is not a correlation estimated from these participants, and it does not change a reported interval.
