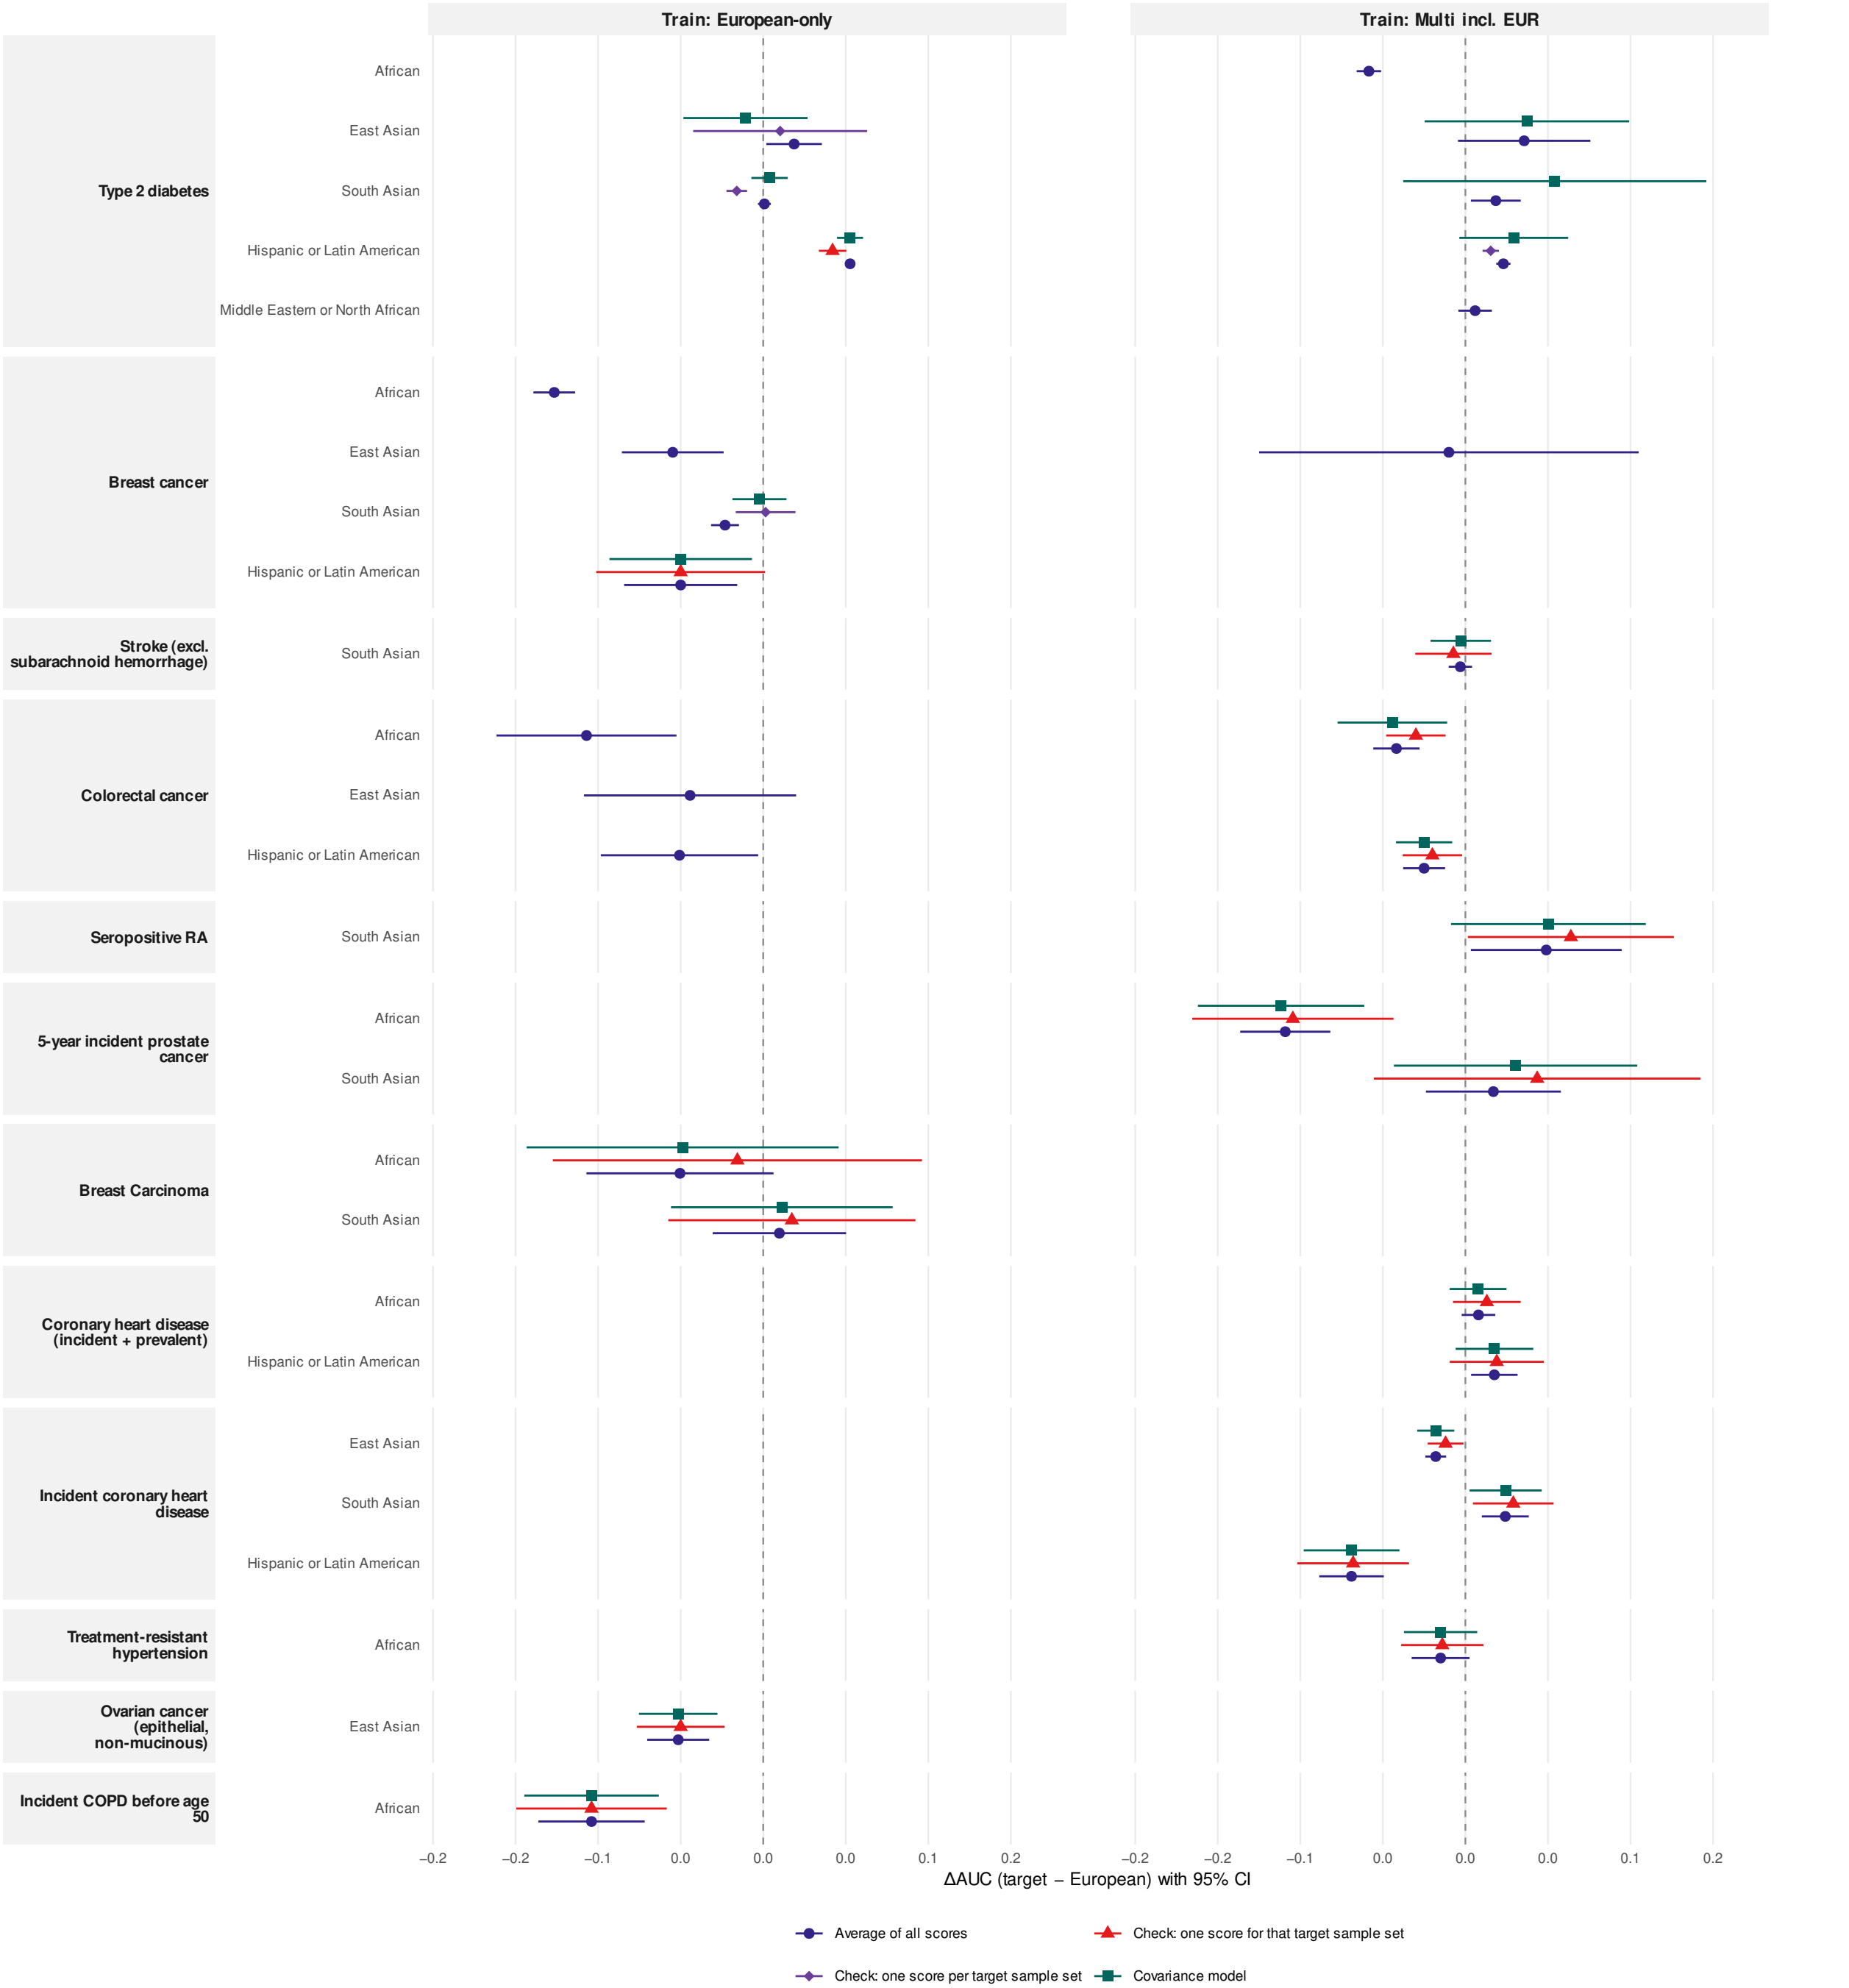
Average of all scores and the covariance model

10 of 24 comparisons with shared samples still exclude zero under the covariance model.
With one sharing group, the interval depends on the assumed ρ; we show 0.3–0.9.



Average of all scores: inverse-variance average on the delta-method standard errors. The covariance model is fit only where scores share people, with ρ = 0.6.
Check, one score for that target sample set: those scores share one target sample set; the point is the retained score (lowest PGS ID).
Check, one score per target sample set: shown where at least two scores remain and a duplicate is dropped. Comparisons with no shared people are drawn as the average of all scores.
