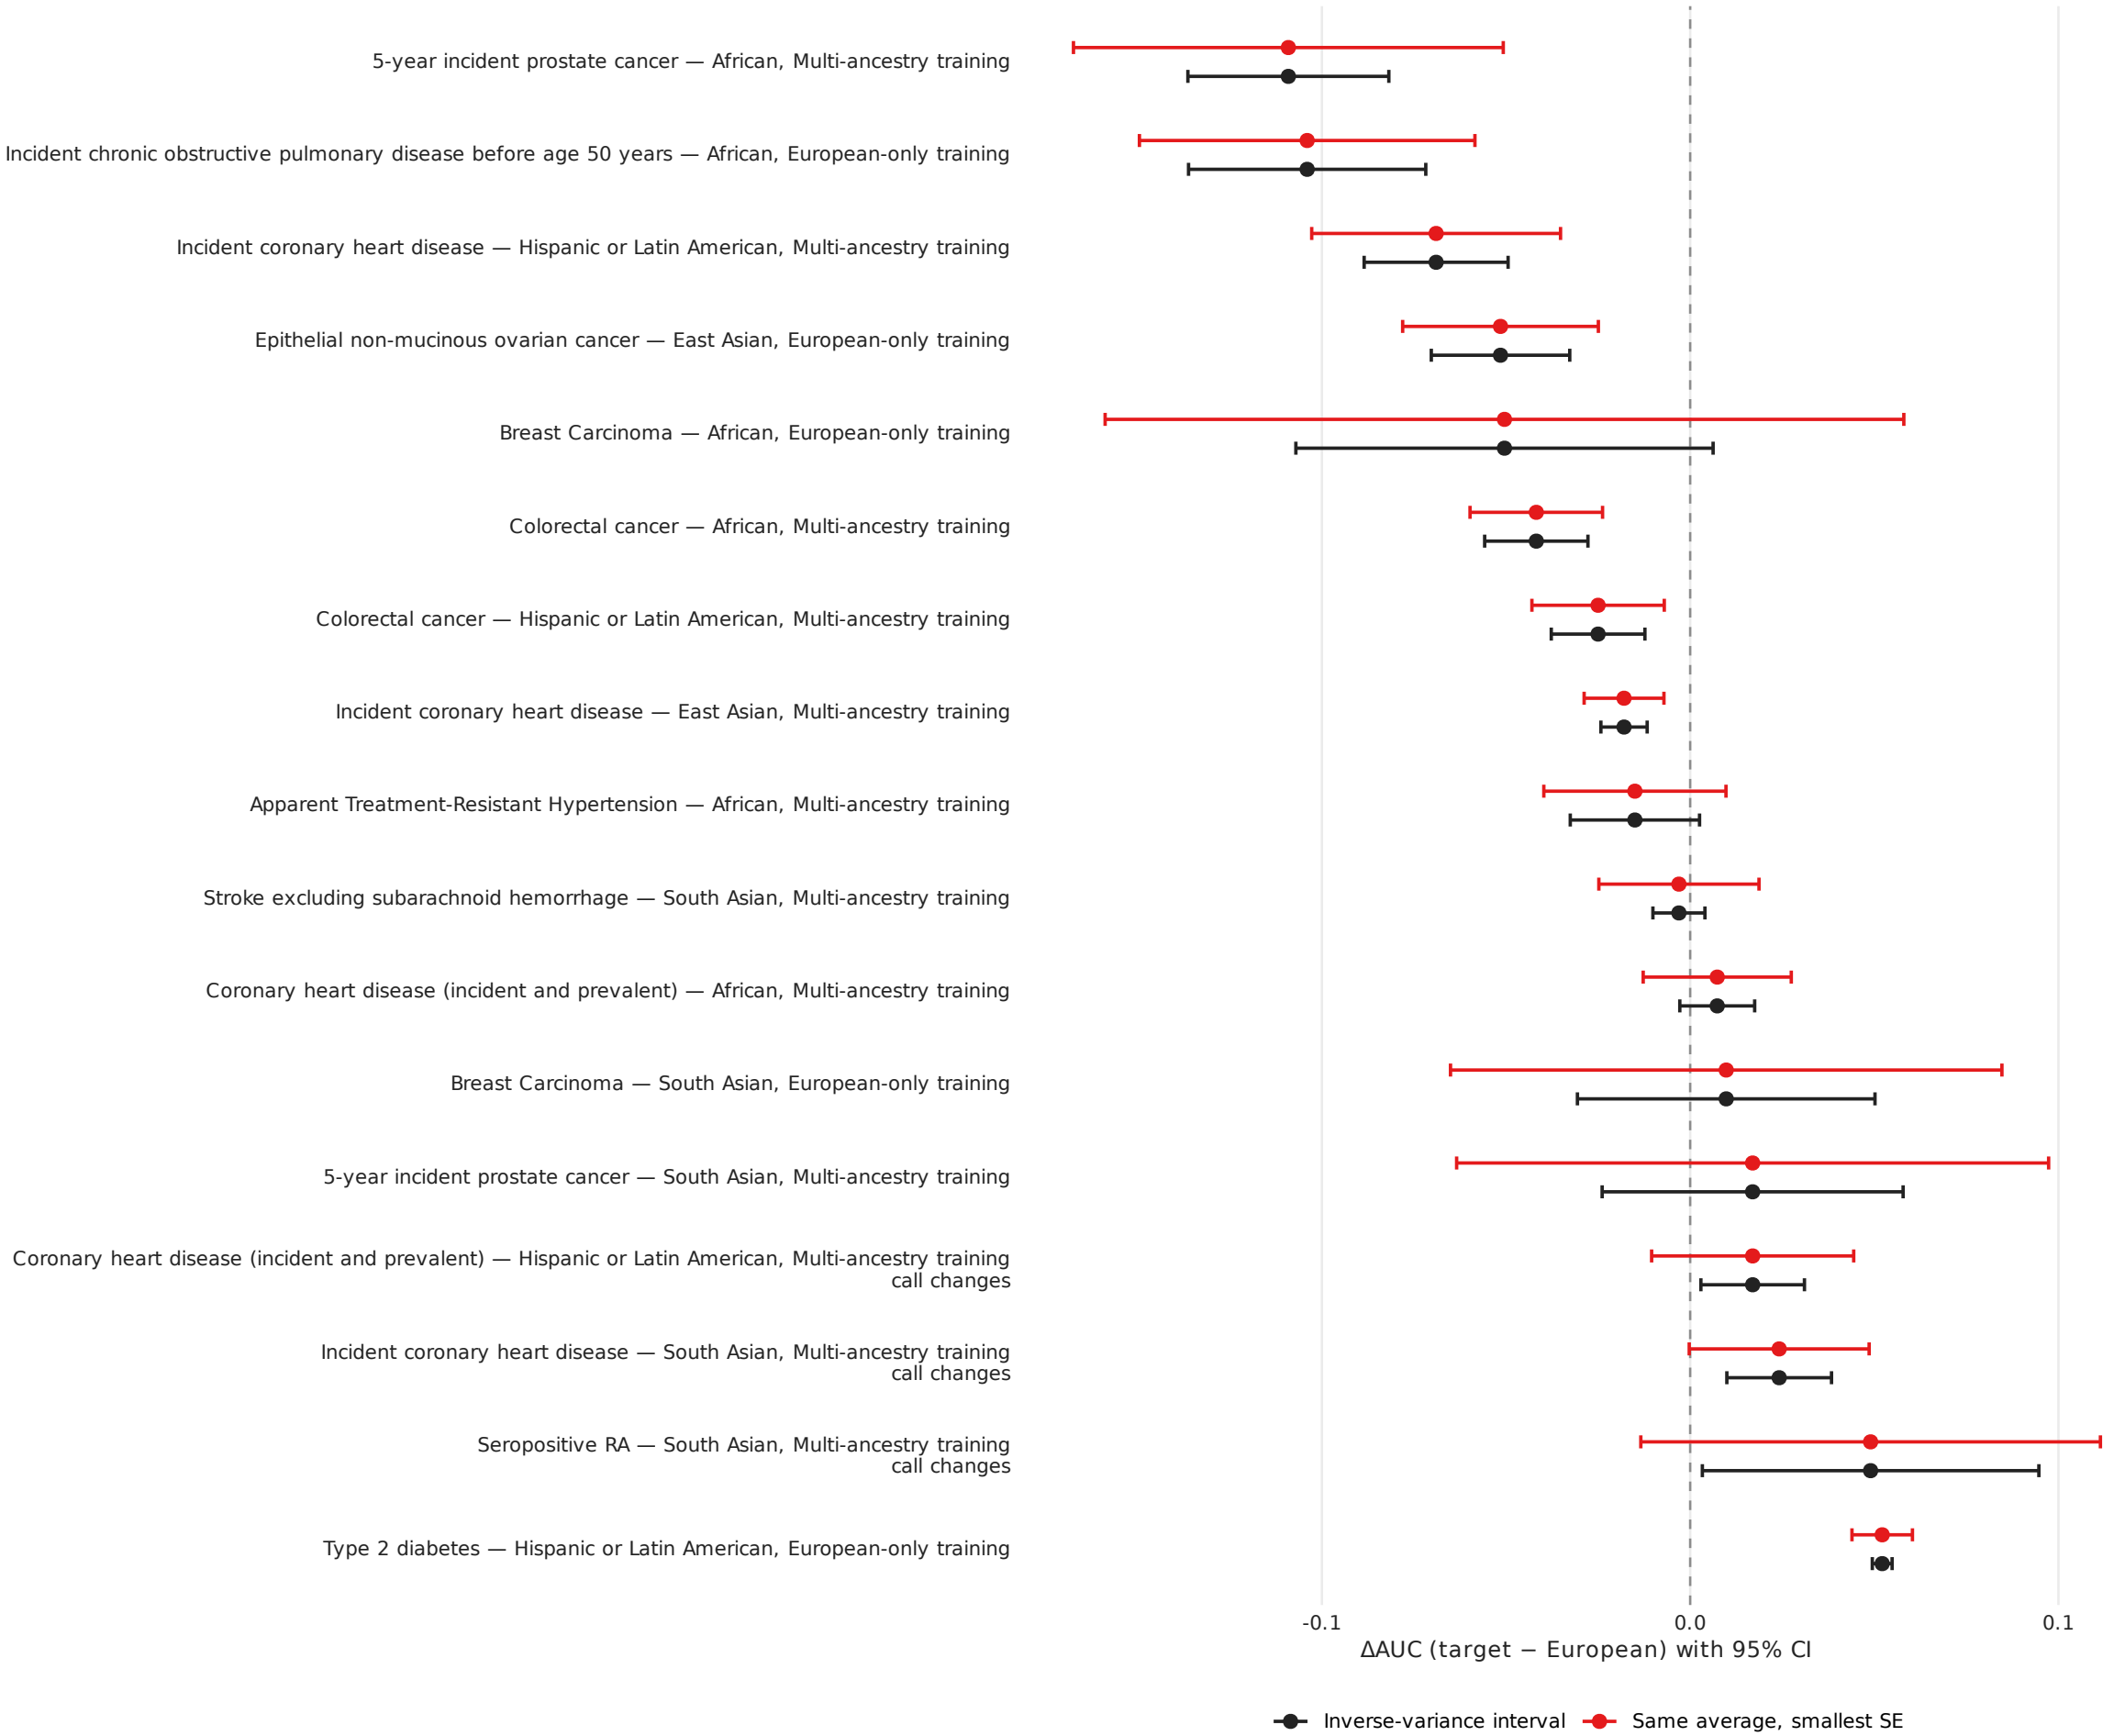
4. The seventeen. The point stays. The interval returns to one score.

Black is the inverse-variance interval. Red is the same average with the smallest standard error among the scores.
Three red intervals include 0 where the black interval does not.



The three whose call changes are coronary heart disease, incident and prevalent, in Hispanic or Latin American participants; incident coronary heart disease in South Asian participants; and seropositive rheumatoid arthritis in South Asian participants. Stroke has two South Asian sample sets. All ten scores use both, so one key remains and the cohort model still has a single ancestry difference. The median standard error gives the same call as the smallest in all seventeen.
