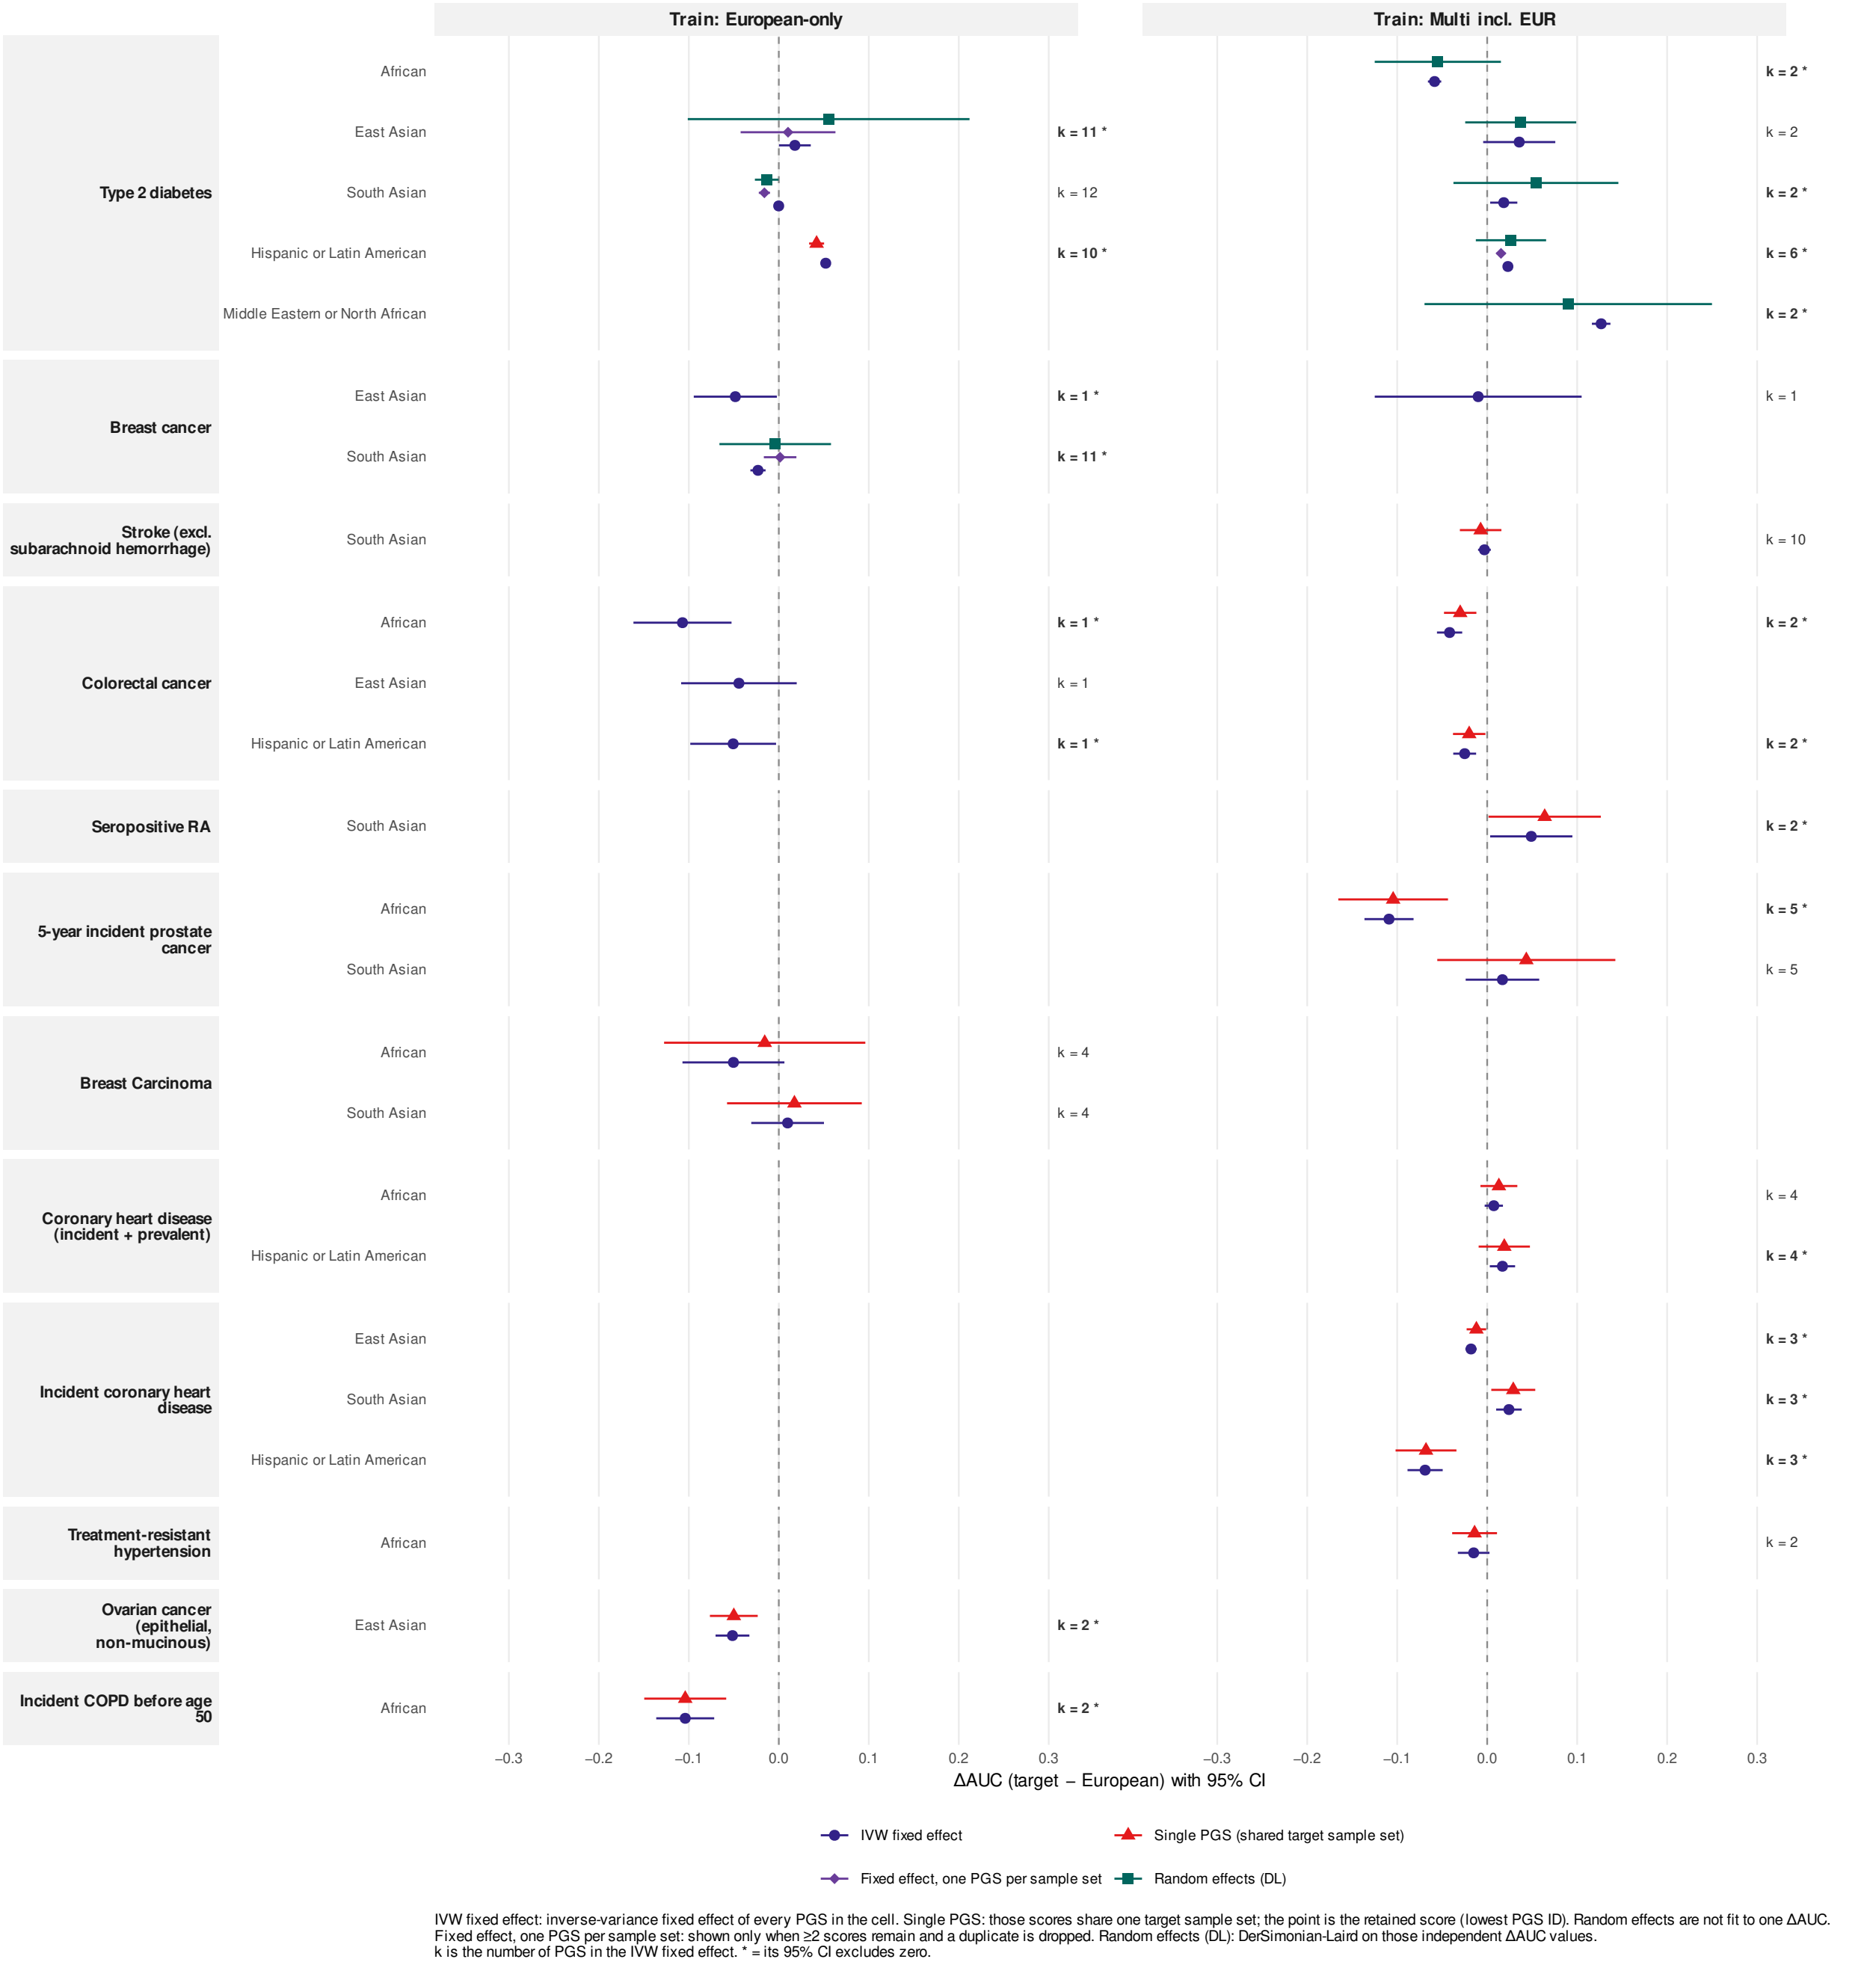
Dependence sensitivities on the delta-method ΔAUC

95% CI excludes zero for 20 IVW fixed effects. Single-PGS sensitivity (k > 1, one target sample set): 10 of 17.
Random effects, only where ≥2 independent ΔAUC remain: 1 of 8 exclude zero. 5 cells are one ΔAUC and are drawn once.



IVW fixed effect: inverse-variance fixed effect of every PGS in the cell. Single PGS: those scores share one target sample set; the point is the retained score (lowest PGS ID). Random effects are not fit to one ΔAUC.
Fixed effect, one PGS per sample set: shown only when ≥2 scores remain and a duplicate is dropped. Random effects (DL): DerSimonian-Laird on those independent ΔAUC values.
k is the number of PGS in the IVW fixed effect. * = its 95% CI excludes zero.
