

4. The two kept scores are still one target sample, so there is no random effect

African target sample set PSS000331, 7,597 people.
Hispanic or Latin American is the same pattern: both kept scores use one shared target sample set.
A DerSimonian-Laird model needs two or more independent ΔAUC values. Two scores on the same people are one ΔAUC with two versions.

The review figure therefore stops at the red triangle in plot 2: the inverse-variance pool of the two matched pairs.
It does not add a random-effects estimate. The dependence lesson, for type 2 diabetes, is where several target sample sets remain and that model is fit.
