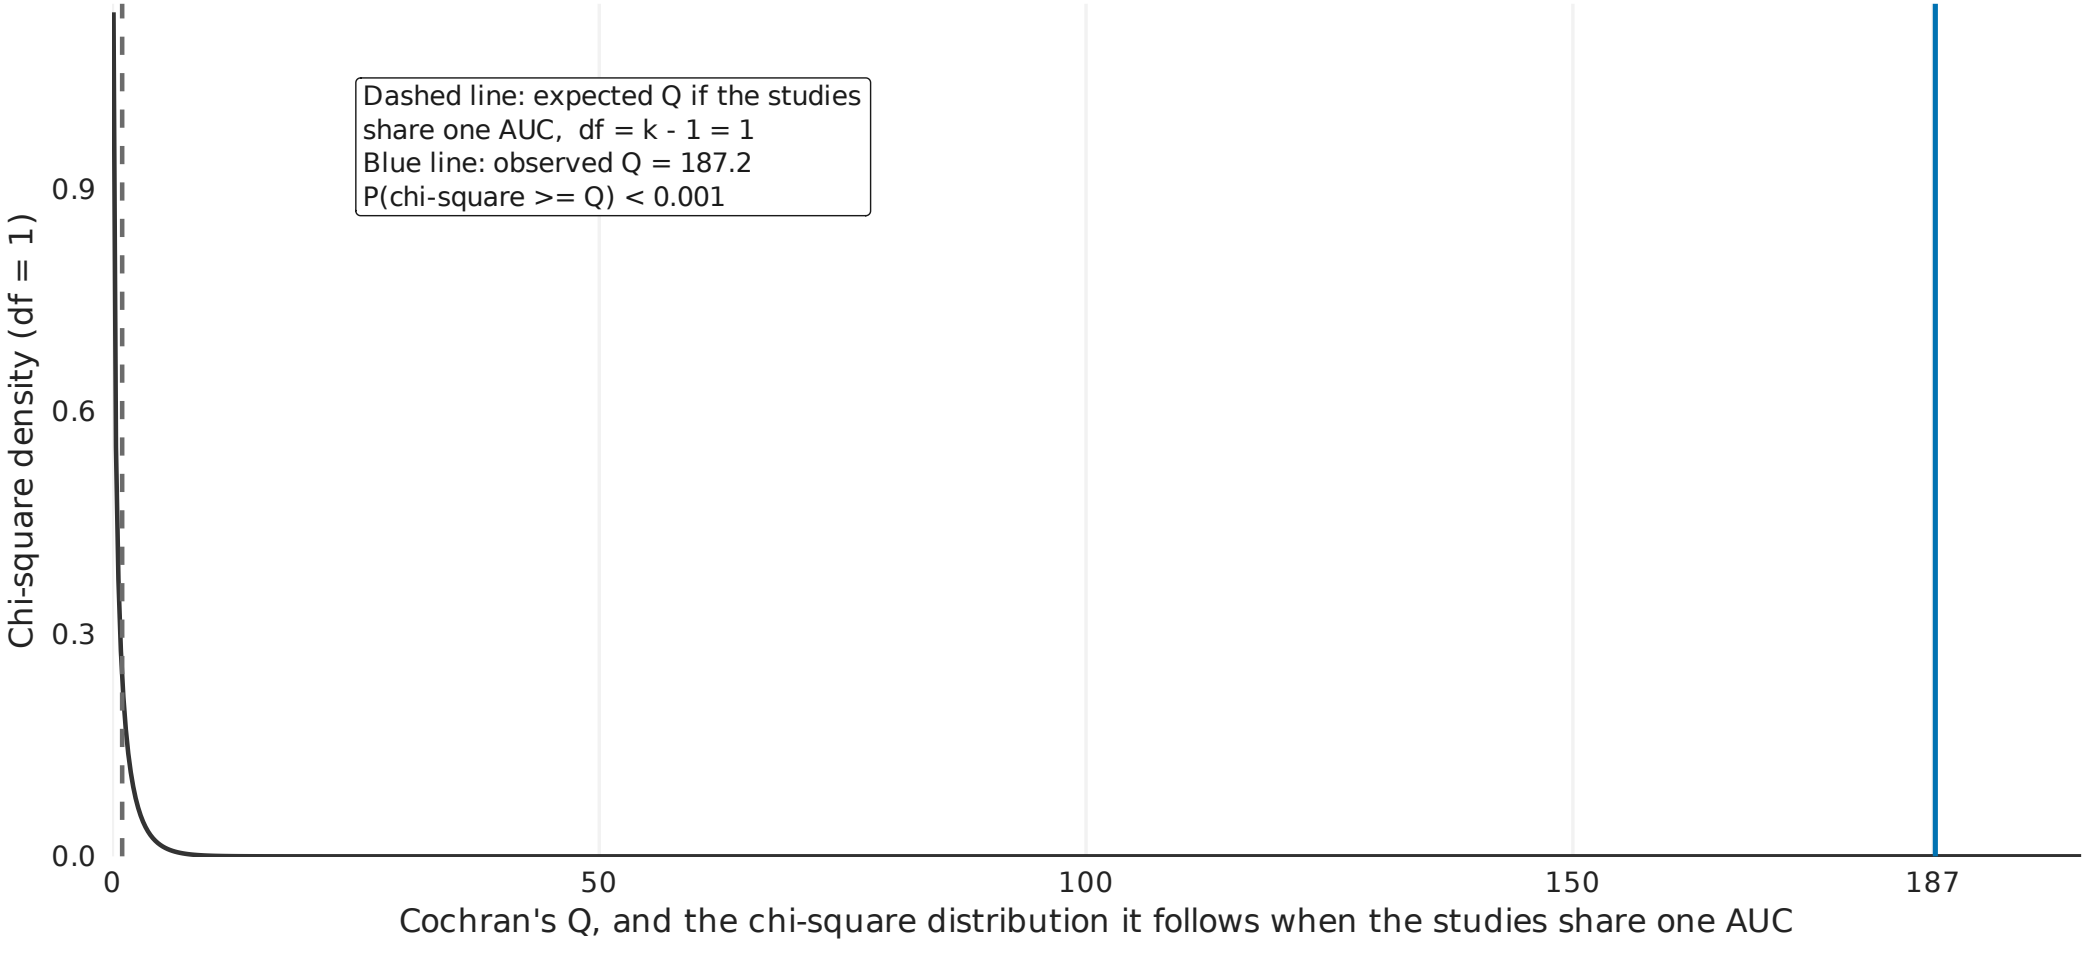
5. Under pure sampling error, Q averages df, not zero

Two studies give one contrast, so df = 1. Chance alone produces a Q whose average is 1, not 0.
The observed Q is 187, far to the right of that benchmark.



The chi-square curve is the spike at the left. Almost all of its area sits between 0 and 5.
A Q of 187 is not a chance fluctuation of two studies that share one AUC. The p-value is below 0.001.
