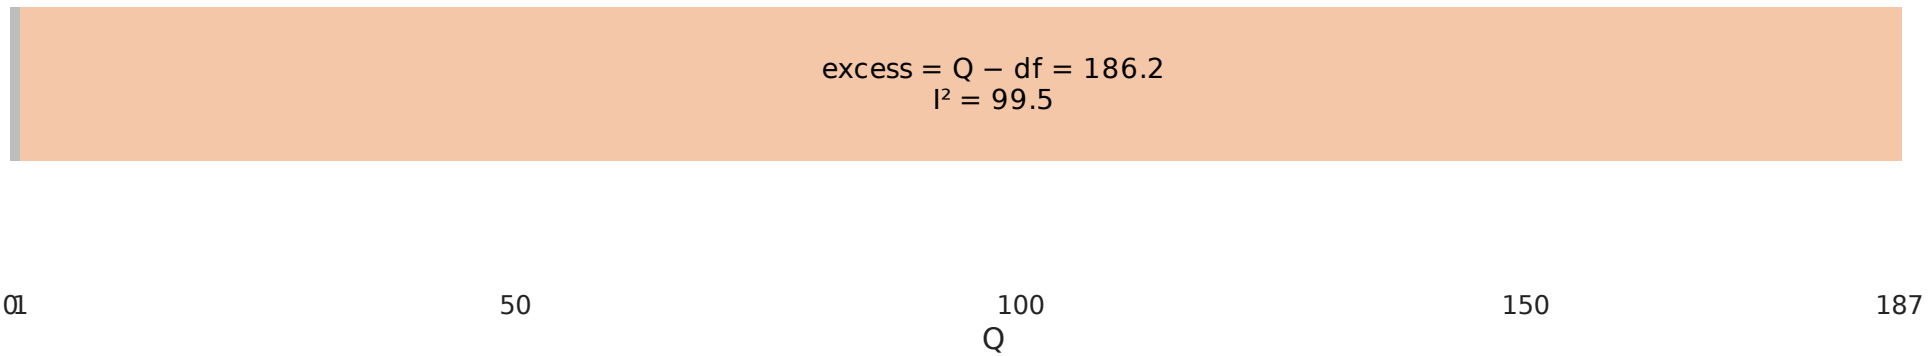
6. I² corrects Q by removing the scatter chance is expected to produce

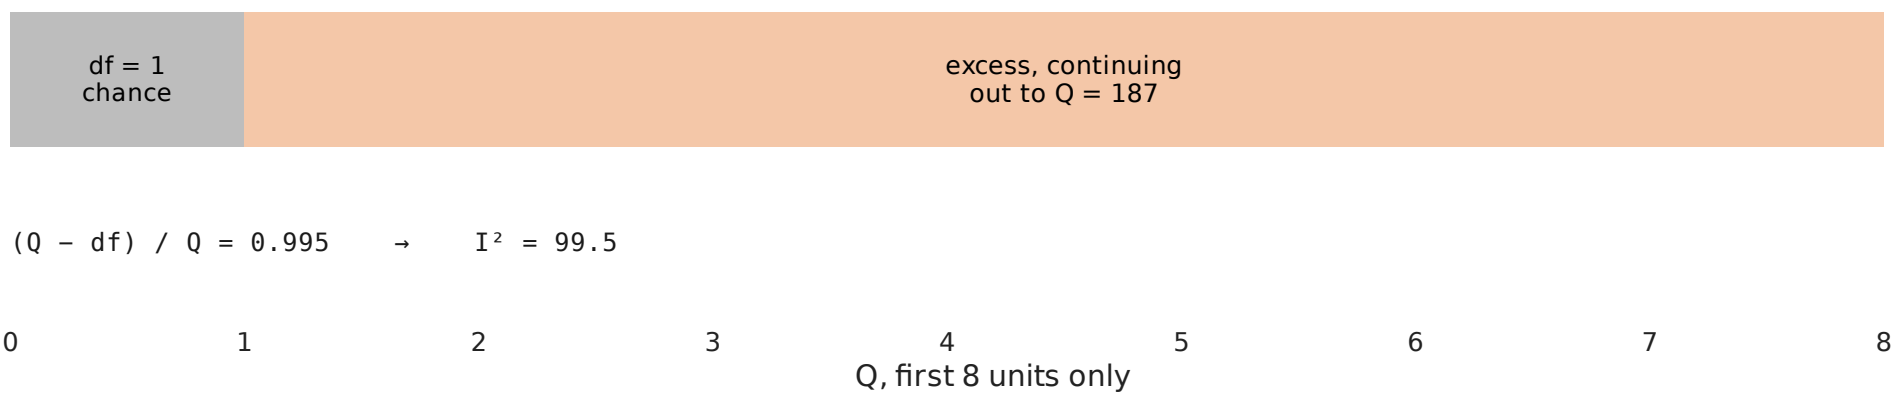
I² = max(0, (Q - df) / Q) × 100.
The numerator drops df, the average Q when sampling error is the only difference.
What remains is a percent of Q. Here that percent is 99.5.

PGS000004, the real Q

Whole bar = observed Q = 187.2. Grey edge at the left = df = 1.



Left edge of the same bar, zoomed



I² does not move the pooled AUC. The pooled AUC stays 0.645.
I² = 99.5 means almost all of Q is heterogeneity beyond sampling error, so this European cell is removed by the I² filter before Figure 1C.
The eMERGE logit, 0.405, is the European number in the Stage-2 scale check. Q here is the within-ancestry scatter, computed after the second study is included.
