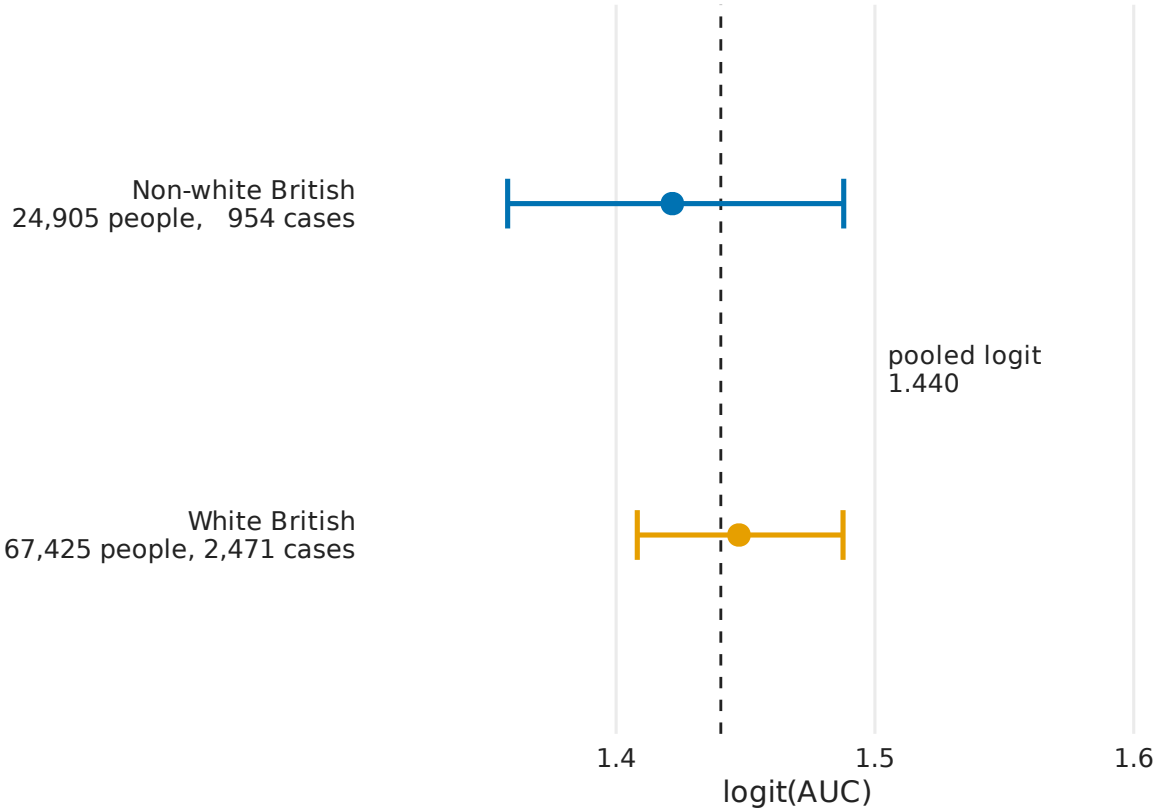
2. Q is computed on the logit of AUC, not on AUC itself

A difference of 0.01 in AUC is not the same precision everywhere between 0 and 1.
The logit is the scale on which the weights, the mean, and Q are calculated.

Both studies on the logit scale



```
Basic functions, one study at a time

Non-white British
  AUC = 0.80561
  eta = log(AUC / (1 - AUC)) = 1.422
  logit interval = 1.358 to 1.488
  SE = (upper - lower) / (2 x 1.96) = 0.0331

White British
  AUC = 0.80961
  eta = log(AUC / (1 - AUC)) = 1.447
  logit interval = 1.408 to 1.488
  SE = (upper - lower) / (2 x 1.96) = 0.0203

The larger study has the narrower interval,
so its SE is smaller. That is the only reason
it will receive more weight.
```

The dashed line is the weighted mean of the two logits. Mapping it back with plogis() returns the pooled AUC in plot 1.
